

Problem 5 (due Monday, November 8)

We call a positive integer N **prosperous** if $\phi(N) + \sigma(N) = 2(N+1)$ and $\phi(N)\sigma(N) = (N-5)(N+3)$. Knowing that both N and $N-504$ are prosperous, find N .

Remark. Here ϕ is the Euler function and σ is the sum of divisors:

$\phi(N)$ = the number of positive integers which are relatively prime to N and do not exceed N ,

$\sigma(N)$ = the sum of all positive divisors of N .

These functions are studied in elementary number theory (a topic of Math 407). They both are so called **multiplicative functions**: for any two **relatively prime** integers M, N we have $f(MN) = f(M)f(N)$, where f is either ϕ or σ .

We received solutions from Ashton Keith, Maxwell T Meyers, and Pluto Wang. Ashton provides a short solution which requires some direct computations at the end. Maxwell shows that the first condition in the definition of a prosperous number holds for M if and only if $M = pq$ is a product of two distinct prime numbers. From this he concludes that M is prosperous if and only if $M = p(p+4)$ where both p and $p+4$ are prime numbers. From this he shows that $N = 2021$ is the only solution to the problem. Pluto has a partial solution, which proves what Maxwell showed but only when M is a product of distinct prime numbers (i.e. M is square-free). Maxwell's solution is the same as my original solution. However, I later realized that the second condition in the definition of the prosperous number implies the first one. For more details see the following link [Solution](#).
